Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).

Description

The present invention relates to a method and apparatus for perforating a well, more particularly to a method and apparatus for perforating a well in response to pressure in a first tubing string and producing the formations through a second tubing string or through the casing. The present invention is particularly advantageous when multiple formations are desired to be perforated and produced together.

In oil and gas wells, it is often desirable to obtain production from multiple zones in a single well. In such wells, it may be desirable to perforate and produce from more than one formation within a single zone. Particular problems may be encountered when these formations are widely spaced. For example, it is known to perforate and produce formations located a thousand feet or more apart as a single zone. Difficulties presented in such situations include, for example, difficulties in obtaining reliable actuation of the detonating mechanism for the perforating guns, and particularly doing so while maintaining a desired underbalance on the formations at the time of perforating.

Additionally, in many operations it is preferable to detonate the perforating guns through use of hydraulic pressure rather than by passing a mechanical detonating mechanism, such as a detonating bar, or "go devil," through the tool string. It is also preferable to have spare firing mechanisms to optimize reliability of detonation of the perforating guns. Prior art techniques utilizing spare (redundant) firing mechanisms have required the pressurization of the annulus in the well adjacent the zone to be perforated. Such pressurization of the annulus can eliminate the ability to establish a desired pressure balance, typically an underbalance, between the perforated formation and the wellbore, to obtain optimal perforation of the formation.

We have now devised a new method and apparatus for reliably perforating one or more formations in response to fluid pressure in a first tubing string while allowing the pressure differential between the formation and the wellbore to be established by a fluid column in a second tubing string or in the casing, through which the perforated formation may be flowed or produced. The present invention also facilitates the use of spare firing mechanisms to maintain reliability of the perforating system. Additional formations, even when widely spaced, may be perforated without diminishing reliability of the system. Additionally, the first tubing string may be utilized to produce a second zone in the well.

According to the invention, there is provided an apparatus for perforating a well, comprising: a

packer; a first tool string extending through said packer and including at least one perforating assembly, said perforating assembly comprising, a tubing string, a first firing head assembly actuatable by fluid pressure in said tubing string, a second firing head assembly actuatable by fluid pressure in said tubing string, a perforating gun operatively coupled proximate one end to said first firing head and operatively coupled proximate a second end to said second firing head; and a second tool string providing a passageway for the flow of fluid from a location beneath said packer to the surface.

The invention further includes a method of perforating a well and a formation surrounding said well, comprising the steps of providing in said well a first tool string comprising a tubing string, a first firing head responsive to fluid pressure in said tubing string, a second firing head responsive to fluid pressure in said tubing string, and a perforating gun operatively coupled proximate one end to said first firing head and operatively coupled proximate second end to said second firing head; providing a second tool string in said well; establishing a pressure in said well adjacent said zone to be perforated through use of said second tool string; and causing said first and second firing heads to be actuated by establishing a fluid pressure in said first tool string.

In one aspect, the present invention provides an apparatus for perforating a well which includes two tool strings. The first tool string includes at least one perforating assembly. The perforating assembly preferably includes a tubing string, which defines a first fluid passageway. In a particularly preferred embodiment, the perforating assembly will include suitable apparatus for providing a second, coextensive, assembly, relative to said tubing string. This coextensive assembly will include an upper firing head coupled to the upper end of a perforating gun, and a lower firing head coupled to the lower end of the perforating gun. Each firing head will be of a type actuatable by fluid pressure within the tubing. In a particularly preferred embodiment, each firing head will be of a type where a locking or retaining mechanism is released in response to pressure in the tubing string and where actual detonation of the firing head is accomplished in response to annulus pressure in the well. Additionally, a flow path for the perforated formation will preferably be established by a second tool string, which may be merely a tubing string, which extends to a location proximate the formations to be perforated. Preferably, both the first tool string and the second tool string will extend into a zone which is isolated at its upper end by a packer.

The present invention also includes the use of two or more perforating assemblies as described

above in the first tool string. Additionally, the first tool string may include one or more additional packers to isolate a second zone in the well. In a preferred embodiment this arrangement would facilitate the actuation of perforating guns through pressure in the first tool string and also the flowing or production of the second zone along the passageway of the first tool string.

In order that the invention may be more fully understood, embodiments thereof will now be described by way of example only, with reference to the accompanying drawings, in which:

FIGURES 1A-B depict an embodiment of perforating equipment assembly in accordance with the present invention, disposed within a well, illustrated partially in vertical section.

FIGURES 2A-B depict elements of the perforating assemblies as shown in FIGURE 1 in greater detail, and partially in vertical section.

FIGURES 3A-B depict a firing head assembly of FIGURE 2B in greater detail and partially in vertical section.

FIGURE 4 depicts the actuation mechanism of FIGURES 2B and 3B in greater detail and partially in vertical section.

FIGURE 5 schematically depicts components of the detonation mechanism of FIGURE 5 in an exploded view.

FIGURE 6 depicts a portion of the detonation mechanism of FIGURE 5A along lines 6-6, in horizontal section.

FIGURE 7A-B depict an alternative firing head assembly in accordance with the present invention, illustrated partially in vertical section.

Referring now to Figures 1A-B, therein is schematically depicted one example of a perforating equipment assembly 10 established in accordance with the present invention and situated inside a well 12 in which casing 13 has been set. Well 12 includes an upper zone 14 and a lower zone 16. Upper zone 14 is adjacent two spaced formations to be perforated, 18 and 20. Lower zone 16 is adjacent a single formation to be perforated 22.

Perforating equipment assembly 10 includes a long string assembly 24 and a short string assembly 26, coupled together by a dual packer 28. Dual packer 28 may be of any conventional type, and, as will be apparent from the discussion to follow, may be either mechanically or hydraulically set. Short string 26 may be simply a string of tubing coupled to dual packer 28 to form a flow path. However, for practical reasons, a nipple seating profile 30 or other closure device will preferably be provided in short string 26. It should be clearly understood that the term "tubing" as used herein may refer to drill pipe, completion tubing, production tubing or other similar tubular members suitable for forming the flow paths described and illus-

trated herein. Similarly, unless identified otherwise, connections between tubular or housing members will be by way of conventional "pin" and "box" threaded couplings.

Long string assembly 24 includes a tubing string 25, also coupled to dual packer 28. Coupled to tubing string 25 beneath dual packer 28 in long string assembly 24 are two perforating assemblies, indicated generally at 30a and 30b. Each perforating assembly 30a, 30b is functionally identical. A seating profile 31 for a plug may also be included in long string assembly 24. The structure of perforating assemblies 30a and 30b will preferably be essentially identical. However, as will be apparent to those skilled in the art, the length of the perforating gun or guns, indicated generally at 32a, 32b, in each perforating assembly 30a, 30b may be varied to facilitate perforation of the desired interval.

Beneath perforating assemblies 30a and 30b in long string assembly 24 is a packer 34 which isolates upper zone 14 from the lower zone 16 of well 12. Packer 34 may be either carried into the hole as an integral portion of long string assembly 24, or it may be set in the well, such as by wireline, and long string assembly 24 stabbed into it. Beneath packer 34 is a conventional perforating assembly 35 including a perforated nipple 36, a firing head 38 and a perforating gun 40. Perforated nipple 36 can be one of many conventional apparatus adapted to provide a fluid path from lower annulus 37 into long string assembly 24. As will be discussed in more detail later herein, firing head 38 is preferably a hydraulically actuated firing head. However, firing head 38 may also be a mechanically actuated firing head. As can be seen in Figure 1, tubing string 25 extends from the surface, through both perforating assemblies, to perforating assembly 35.

Referring now also to Figures 2A-B, therein are depicted portions of perforating assemblies 30 in greater detail and partially in vertical section. Each perforating assembly 30 extends from an upper branching block, or Y-block, 42 to a lower branching block assembly, or Y-assembly, 56. Y-block 42 and Y-assembly 56 facilitate the establishing of two coextensive strings. A primary string includes one or more lengths of tubing 44 which form a portion of tubing string 25. Tubing string 25 and Y-block 42 and Y-assembly 56 cooperatively define a flow path 46 throughout long string assembly 24. A secondary string includes equipment to perforate the well and components to facilitate assembly of perforating assembly 30. Coupled to Y-block 42 in the secondary string is an adapter sub 48 and a swivel 50. Swivel 50 is included to facilitate assembly of perforating assembly 30 and may be of a conventional type. Preferably, swivel 50 will be a telescoping swivel. Adapter sub 48 is included to

allow the adjustment of the length of the secondary string to facilitate assembly of perforating assembly 30. Located beneath swivel 50 is firing head sub 51 which includes a firing head assembly 52. Firing head sub 51 is then coupled to perforating gun 32. At the lower extreme of perforating gun 32 is Y-assembly 56. Y-assembly 56 also includes a firing head assembly, indicated generally at 58. Y-assembly 56 contains passages 66 which form a fluid path between path 46 and firing head assembly 58. Similarly, Y-block 42 includes a fluid path 43 which allows communication from flow path 46, through adapter sub 48 and swivel 50, to firing head assembly 52.

Firing head assembly 52 is depicted in Figure 2A, while firing head assembly 58 in Y-assembly 56 is depicted in Figure 2B, as well as in Figures 3A-B and 4. Firing head sub 51 and Y-assembly 56 each preferably include housing assemblies, for firing head assemblies 52 and 58, respectively. These housing assemblies include corresponding components, including swivel portions. Additionally, the operating mechanisms of firing head assembly 52 and firing head assembly 58 are preferably identical. Accordingly, only the housing and mechanism of firing head assembly 58 will be discussed herein in detail. Corresponding components in firing head sub 51 and firing head assembly 52 have been identified with identical numerals. Because both firing head assembly 52 and firing head assembly 58 are in fluid communication with flow path 46 in long string assembly 24, firing head assembly 52 and firing head assembly 58 will be responsive, essentially simultaneously, to fluid pressure in flow path 46.

Referring now primarily to Figure 2B, therein is depicted an exemplary Y-assembly 56 in accordance with the present invention, illustrated partially in vertical section. Y-assembly 56 includes a Y-housing 62 and a firing head housing assembly, indicated generally at 63. Y-housing 62 includes conduit 64 which forms a portion of flow path 46, one or more conduits 66a, 66b, and piston chamber 68. Conduits 66a, 66b provide fluid communication between flow path 46 and piston chamber 68.

Firing head housing assembly 63, together with piston chamber 68, and their associated components form firing head assembly 58. Firing head housing assembly 63 includes a ported housing 70 which is coupled to a swivel, indicated generally at 72. Swivel 72 includes a swivel sub mandrel 74 rotatably coupled to ported sub 70 by swivel retainer 76. Swivel sub mandrel 74 couples to housing 78 which is coupled to sub 80 attached to perforating gun 32. Swivel 72 allows housing 78 and components connected thereto to rotate relative to ported sub 70 to facilitate makeup of per-

forating assembly 30. Ports 71 in ported sub 70 facilitate fluid communication between the well annulus surrounding housing assembly 63 and the interior of housing assembly 63. Firing head housing assembly 63', of firing head sub 51, differs from firing head housing assembly 63 in that firing head housing assembly 63' includes a sub 73 in place of Y-block 62.

In this preferred embodiment, firing head assembly 58 is responsive both to tubing string fluid pressure, in flow path 46, and to annulus pressure. Tubing pressure is utilized to unlock the firing mechanism to allow the firing pin to move to strike the initiator charge. However, annulus pressure is utilized to cause the firing pin to actually strike the initiator to cause detonation of the perforating gun.

Firing head assembly 58 includes a detonation mechanism, indicated generally at 82, responsive to an actuation mechanism, indicated generally at 84. Referring now also to Figures 3A-B, therein is depicted detonation mechanism 82 and actuation mechanism 84 in greater detail, and partially in vertical section. Detonation mechanism 82 includes a striking piston 86 retained within a bore 87 in housing 88. Striking piston 86 is longitudinally movable relative to housing 88 but is initially secured in a first position by a shear pin 90. Striking piston 86 includes a first end 92 adapted to receive an impact to shear shear pin 90 and cause longitudinal movement of striking piston 86 relative to housing 88. Striking piston 86 is retained within housing 88 at all times by the cooperation of a notch 94 in striking piston 86 and a pin 96 which cooperatively engages notch 94 and a recessed aperture 98 in housing 88.

Referring now also to Figures 5 and 6, therein are depicted portions of detonation mechanism 82 in greater detail. A second end of striking piston 86, indicated generally at 108, includes a first portion 110 of reduced diameter. Second end 108 of striking piston 86 also includes a second portion 112 of enlarged diameter relative to first portion 110 of striking piston 86. Second portion 112 of striking piston 86 and end portion 115 of housing 88 extend into a recess 113 in firing piston 114. Firing piston 114 is secured in fixed position relative to housing 88 by a plurality of collets 116 which cooperatively engage apertures 118 in housing 88 and recesses 120 in recess 113 of firing piston 114. Collets 116 are held in position by second portion 112 of striking piston 84. Second end 121 of firing piston 114 sealingly engages bore 120 in detonation extension 122, which is coupled to housing 88. A firing pin 123 is secured to second end 121 of firing piston 114. Detonation extension 122 includes ports 125 to assure fluid communication between annulus pressure and firing piston 114.

Firing pin 123 is designed to detonate an initiator charge 126 which is sealingly retained within an enlarged bore 124 in detonation extension 122. The sealing engagement of second end 121 of firing piston 114 with bore 121 and of initiator 126 with bore 124 forms a sealed chamber 128 which will be at atmospheric pressure. Accordingly, second end 121 of striking piston 114 is a fluid responsive piston within bore 120, which is responsive to annulus pressure inside housing assembly 63. Striking piston 86 will be retained by a shear pin 90 which will be selected to shear at a desired actuating pressure as created by actuation mechanism 84.

Coupled to end 130 of detonation extension 122 is a housing extension, indicated generally at 132. Housing extension 132 defines a central aperture 134 which will cooperatively provide a mechanism for communicating the ignition of initiator 126 to perforating gun 32. Preferably, aperture 134 will house a length of an explosive carrier, such as primacord, 136 fitted with a booster charge 138a, 138b at each of its ends. Housing extension 132 will preferably couple to an internal portion of sub 80 which couples, in turn, to perforating gun 32. Booster charge 138b will be housed in sub 80 proximate the coupling with perforating gun 32. Housing 78 couples, at an external portion, to sub 80.

Longitudinal movement of striking piston 86 is caused by actuation mechanism 84. Actuation mechanism 84 includes an actuator piston 140 housed within piston chamber 68 of Y-housing 62. Actuator piston 140 is sealingly received in bore 142 of piston chamber 68, and is retained in bore 142 by a piston retaining ring 144. Piston retaining ring 144 is secured by shear pins 146 to an adjustable shear pin seat 148. Adjustable shear pin seat 148 is threadedly coupled, at 150, to Y-housing 62. As can be seen in Figure 3B, actuator piston 140 is held against seating shoulder 152 by piston retaining ring 144. Threaded adjustment 150 on shear pin seat 148 facilitates the adjustment of the longitudinal placement of piston retaining ring 144 to assure that actuator piston 140 is securely seated against shoulder 152. This secure seating of actuator piston 140 will assure that pressure fluctuation in flow path 46 will not cause unwanted movement of actuator piston 140 which could lead to premature shearing of shear pins 146.

Retained within a longitudinal bore 154 in actuator piston 140 is a telescoping firing rod 156. Firing rod 156 is held in a first longitudinal position relative to actuator piston 140 by a shear pin 158. A lock ring 160 is secured in concentric relation to the path of actuator piston 140 by a lock ring retaining member 162. Actuator piston 140 includes a peripheral groove 164. Lock ring 160 is prefer-

ably a split ring type retaining ring adapted to engage peripheral groove 164 when actuator piston 140 is moved from its resting position to a second, actuated, position, and to thereby secure actuator piston 140 in such second position.

Referring now also to Figure 4, therein is shown actuating mechanism 84 in the second, actuated, position. In operation, firing head assembly 58 operates as follows. Once pressure in flow path 46, and thereby in piston chamber 68 reaches a threshold level, as determined by shear pins 146, actuator piston 140 will shear shear pins 146, and will travel longitudinally toward detonating mechanism 82. Telescoping firing rod 156 will contact striking piston 86 and move it longitudinally. As striking piston 86, is moved, recessed portion 110 of striking piston 86 is brought into coextensive relation with collets 116. The reduced diameter of section 110 allows collets 116 to fall out of engagement with recesses 120 in firing piston 114. Annulus fluid pressure in housing 63, acts, through ports 125, on firing piston 114, driving it longitudinally with sufficient impact to cause firing pin 123 to ignite initiator 126. In a preferred embodiment, 1000 psi (6.89MPa) annulus pressure is sufficient to drive firing piston 114. Those skilled in the art will recognize that firing head assembly 58 may therefore be actuated by much lower annulus pressure than is required by conventional annulus pressure firing heads. Additionally striking piston 86 does not have to be shear pinned at a level above anticipated annulus hydrostatic pressure, which may be difficult to anticipate with precision.

Initiator 126 will ignite and communicate its ignition through booster charge 138a, primacord 136 and booster charge 138b to detonate a similar booster charge (not illustrated) in perforating gun 32. Accordingly, the mechanical actuation of striking piston 86 releases firing piston 114 and allows the well annulus pressure to drive firing piston 114 with a substantial force to assure sufficient impact for ignition of initiator 126.

When striking piston 86 provides an established resistance to the movement of firing rod 156, as determined by shear pin 158, shear pin 158 will shear, and telescoping firing rod 156 will move longitudinally into bore 154. When actuator piston 140 approaches the end of its range of travel, lock ring 160 will engage recess 164 in actuator piston 140 and lock it in position. Thus, telescoping firing rod 156 will be retained within bore 154, but without any solid connection by which it could apply additional force to striking piston 86. Telescoping firing rod 156 also serves as a lost motion device to avoid excessive shock to detonation mechanism 82. Similarly, actuator piston 140 will be locked in a fixed position within bore 142. Accordingly, subsequent changes in the pressure differential between

the borehole annulus and in flow path 46 will not cause movement of actuator piston 140, and therefore wear of seals 162 between actuator piston 140 and bore 142. Accordingly, a secure seal will be maintained between the interior of housing assembly 63 and flow path 46.

Referring now to Figures 7A-B, therein is depicted an alternative embodiment of a firing head assembly, in particular a time delay firing assembly, indicated generally at 180, suitable for use with the present invention. Time delay firing assembly 180 is responsive to the same actuation mechanism 84 as used with firing head assemblies 52 and 58. Additionally, time delay firing assembly 180 utilizes a detonation mechanism, indicated generally at 182, which is substantially identical to that used in firing assemblies 52 and 58. Accordingly, corresponding components have been numbered identically. As will be apparent from the discussion to follow, in the time delay firing assembly firing pin 114 will impact a primer assembly 192 rather than an initiator. Time delay firing assembly 180 is contained within a housing assembly 181 which is preferably similar to housing assembly 63 of firing head assembly 58. As is apparent from the Figures, housing assembly 181 differs from housing assembly 63 only slightly to accommodate different internal components and to facilitate assembly.

In time delay firing assembly 180, second end 182 of housing 88 is preferably threadably coupled to a detonation block 184. Detonation block 184 is sealingly received within a sleeve 186. Similarly, sleeve 186 is sealingly received within a bore 188 in lower housing 190.

Located at the end of detonation block 184 is a primer assembly 192. Primer assembly 192 is a conventional ignition charge adapted to ignite upon impact by firing pin 123. Primer assembly 192 is secured to detonation block 184 by a primer block 194 which is preferably boltably secured to sleeve 186. Primer block 194 includes a passage 196 which allows the jet of hot gasses emitted by the ignition of primer assembly 192 to enter a chamber 198 in housing 190. Secured within chamber 198 is a delay element assembly 200. Delay element assembly 200 is preferably threadably secured at 202 to a receiving block 204 which is sealingly received within a bore 206 in housing 190. Chamber 198 and the portion of bore 208 in detonation block 184 beyond firing piston 114 will be at atmospheric pressure.

Delay element assembly 200 is a pyrotechnic device which, upon ignition of an internal initiator will burn for a period of time until detonating an explosive charge to detonate a booster charge to detonate the perforating gun. In a presently preferred embodiment, delay element assembly 200

will burn for approximately seven minutes after initial ignition. However, other delay times clearly may be utilized. The structure of a delay element assembly suitable for use with the present invention is described in U.S. Patent No. 4,632,034 issued December 30, 1986 to Colle, Jr. The specification of U.S. Patent No. 4,632,034 is incorporated herein by reference.

Coupled to lower end of housing 190 is a sub 209 which includes a central bore 210. Sub 209 is coupled to perforating gun 32. Contained within bore 210 is a length of primacord 212 which extends through perforating gun 32 (not illustrated) and includes a booster charge 214 at first end. Booster charge 214 and primacord 212 facilitate detonation of the perforating gun in a conventional manner.

Time delay firing assembly 180 operates similarly to firing head assembly 58. Once firing piston 114 is released, firing pin 123 will impact primer assembly 192. The jet of gasses and hot particles expelled through aperture 196 by the ignition of primer 192 ignites an ignitable pellet in delay element assembly 200, initiating the time delay burn. When the burn has completed its traversal of time delay assembly 200 an explosive pellet in delay element assembly 200 will detonate, causing detonation of booster 214 and primacord 212 to detonate perforating gun 32 in a conventional manner.

Completion of a well through use of completion equipment assembly 10 may be accomplished as follows. Packer 34 may be placed in the well at a desired location between upper zone 14 and lower zone 16. Packer 34 may be set in any desired manner, such as on wireline or on drill pipe, or may be run in the well 12 as a component of long string assembly 24. If packer 34 is set independently, long string assembly 24 is then run into the well, perforating assembly 35 is stabbed through packer 34, and the string is positioned on depth. If desired, a radioactive marker may be included within long string assembly 24 and long string assembly may be positioned on depth in reference to such marker. Once the string is positioned on depth, dual packer 28 will be set. Short string 26 may then be appropriately coupled to dual packer 28, such as by stabbing into packer 28 with an appropriate seal assembly.

Where dual packer 28 is a hydraulically set packer, the packer will preferably be set in response to pressure within short string assembly 26. In such case, the packer may be tested by inserting a plug 33 into profile 30 to close the short string bore through dual packer 28 and by applying pressure in short string 26. Subsequently, the plug 33 may be removed, and pressure may again be applied down short string 26 to test the packer. As another alternative, where dual packer 28 is to be

set in response to pressure in long string assembly 24, it may be desirable to include a profile 31 engagable with a plug in long string assembly 24 such that pressure in long string 24 may be restricted to tubing situated above perforating assemblies 30a and 30b during the packer setting operation.

Because upper zone 14 will be produced through short string 24, underbalance, or overbalance, on upper zone 14 may be established by a desired fluid column in short string 26. The desired under or overbalance may be established by conventional techniques such as locating the desired fluid column in short string 26 as it is placed in the well, or by swabbing, etc. The only pressure requirement for operating perforating assemblies 30a and 30b is that there be a threshold hydrostatic pressure at the depth of upper perforating assembly 30 which is sufficient to actuate the piston of the firing assembly utilized once the piston has been released in response to pressure in long string 24.

When it is desired to perforate upper zone 14, a first pressure may be established in long string assembly 24. This first pressure will be the threshold pressure necessary to shear shear pins 106 in the firing head subs 51 and firing head assemblies 58 in each perforating assembly 30a and 30b. As described with respect to the firing head assemblies, when the threshold pressure is achieved, the striking piston of each firing head assembly will move allowing the annulus hydrostatic pressure to drive the annulus pressure responsive piston, causing detonation of the initiator charge, and consequently, detonation of the perforating guns.

When the perforating guns detonate and the formation and casing are perforated, the flow of the formations will be determined by the pressure established in short string 26. Accordingly, there is no need to bleed off pressure from long string 24 or to perform any mechanical manipulations to allow upper zone 14 to flow or produce freely.

In a particularly preferred embodiment, lower zone 16 will be perforated subsequent to upper zone 14. When it is desired to perforate lower zone 16, a second, greater, pressure may be established in long string 24 which will actuate a hydraulic firing head 38 in perforating assembly 35 to detonate perforating gun 40. Lower zone 16 may then be flowed or produced independently of upper zone 14 through long string 24.

Many modifications and variations may be made in the techniques and structures described and illustrated herein without departing from the present invention. For example, the firing head assemblies in each perforating assembly may be adapted to detonate at different pressures in long string 24. In such an embodiment, the perforating

assemblies may be selectively activated to perforate formations in the zone. Accordingly, it should be clearly understood that the embodiments described and illustrated herein are exemplary only and are not to be considered as limitations on the scope of the present invention.

Claims

1. An apparatus for perforating a well, comprising: a packer (28); a first tool string (24) extending through said packer and including at least one perforating assembly (30a), said perforating assembly comprising, a tubing string (25), a perforating gun (32,32a), a first firing head assembly (52) actuatable by fluid pressure in said tubing string, characterised in that it further comprises a second firing head assembly (58) actuatable by fluid pressure in said tubing string, said perforating gun (32;32a) operatively coupled proximate one end to said first firing head and operatively coupled proximate a second end to said second firing head; and a second tool string (26) providing a passageway for the flow of fluid from a location beneath said packer to the surface.
2. Apparatus according to claim 1, wherein said first tool string further comprises: a second packer (34), said second packer being located beneath said perforating assembly; a second perforating gun (40) coupled beneath said second packer; means (38) operatively coupled to said second perforating gun for activating said second perforating gun; and a ported member (36) coupled in said tool string to provide a flow path from beneath said second packer into said first tool string.
3. Apparatus according to claim 1 or 2, wherein said first tool string further comprises a second perforating assembly (30b), said second perforating assembly comprising: a third firing head assembly actuatable by fluid pressure in said tubing string; a fourth firing head assembly actuatable by fluid pressure in said tubing string; and a second perforating gun (32b) operatively coupled proximate one end to said third firing head assembly and operatively coupled to proximate said second end to said fourth firing head assembly.
4. Apparatus according to any preceding claim, including at least one firing head (52,58) comprising: a housing (62,63) including first (68) and second chambers, said first chamber (68) in fluid communication with a said tubing string (46) and said second chamber in fluid commu-

nication with the well annulus surrounding said firing head; an actuator piston (140) movably responsive to fluid pressure in said first chamber housing; and a detonation assembly (82) comprising, a firing piston (114), a locking assembly (116) for retaining said firing piston in a first position, said locking assembly being releasable by movement of said actuating piston, means for causing movement of said striking piston in response to pressure in said second chamber of said housing after said locking assembly is released.

5. Apparatus according to claim 4, wherein said means for causing movement of said striking piston in response to pressure in said second chamber comprises a third chamber (128) on one side of a portion of said striking piston, said third chamber being at substantially atmospheric pressure.

6. A method of perforating a well (12) and a formation (18,20) surrounding said well, comprising the steps of providing in said well a first tool string comprising a tubing string (24), a first packer (28), a perforating gun (32) a first firing head (52) responsive to fluid pressure in said tubing string, characterised in that a second firing head (58) is responsive to fluid pressure in said tubing string, and said perforating gun (32) is operatively coupled proximate one end to said first firing head and operatively coupled proximate a second end to said second firing head; and in the further steps of providing a second tool string (26) in said well said second tool string providing a flow path from beneath said first packer to the surface; establishing a pressure in said well adjacent said zone to be perforated through use of said second tool string; and causing said first and second firing heads to be actuated by establishing a fluid pressure in said first tool string.

7. A method according to claim 6, wherein said first tool string further comprises a second packer (34) located beneath said first zone to be perforated; a perforating gun (40) coupled beneath said second packer; a firing head (38) operatively coupled to said perforating gun; and a ported member (36) to establish a flow path from beneath said second packer into said first tool string.

8. A method according to claim 6, and 7, wherein said first tool string further comprises a third firing head responsive to fluid pressure in said tubing string; a fourth firing head responsive to fluid pressure in said tubing string; and a sec-

ond perforating gun (32b) operatively coupled proximate one end of said third firing head and operatively coupled proximate a second end to said second firing head.

Patentansprüche

1. Vorrichtung zum Perforieren einer Bohrung, enthaltend einen Packer (28); einen ersten Werkzeugstrang (24), der durch den Packer verläuft und wenigstens eine Perforieranordnung (30a) enthält, die einen Rohrstrang (25), eine Perforierkanone (32, 32a) und eine erste Zündkopfanordnung (52) aufweist, die durch Fluiddruck in dem Rohrstrang betätigbar ist, dadurch gekennzeichnet, daß die Vorrichtung ferner eine zweite Zündkopfanordnung (58) aufweist, die durch Fluiddruck in dem Rohrstrang betätigbar ist, daß die Perforierkanone (32, 32a) an einem Ende mit dem ersten Zündkopf und an einem zweiten Ende mit dem zweiten Zündkopf wirkgekoppelt ist, und daß ein zweiter Werkzeugstrang (26) vorgesehen ist, der einen Durchgangskanal für den Fluidfluß von einer Stelle unterhalb des Packers zur Oberfläche bildet.
2. Vorrichtung nach Anspruch 1, dadurch gekennzeichnet, daß der erste Werkzeugstrang weiterhin aufweist: einen zweiten Packer (34), der sich unter der Perforieranordnung befindet; eine zweite Perforierkanone (40), die unter dem zweiten Packer angekoppelt ist; mit der zweiten Perforierkanone wirkgekoppelte Mittel (38) zur Auslösung der zweiten Perforierkanone; und ein in den Werkzeugstrang eingekoppeltes, mit Öffnungen versehenes Glied (36) zur Bereitstellung eines Strömungsweges von unterhalb des zweiten Packers in den ersten Werkzeugstrang.
3. Vorrichtung nach Anspruch 1 oder 2, dadurch gekennzeichnet, daß der erste Werkzeugstrang ferner eine zweite Perforieranordnung (30b) enthält, die aufweist: eine dritte Zündkopfanordnung, die durch Fluiddruck in dem Rohrstrang betätigbar ist; eine vierte Zündkopfanordnung, die durch Fluiddruck in dem Rohrstrang betätigbar ist; und eine zweite Perforierkanone (32b), die an einem Ende mit der dritten Zündkopfanordnung und an dem zweiten Ende mit der vierten Zündkopfanordnung wirkgekoppelt ist.
4. Vorrichtung nach einem der vorstehenden Ansprüche, gekennzeichnet durch wenigstens einen Zündkopf (52, 58), der aufweist: ein Gehäuse (62, 63) mit ersten (68) und zweiten

Kammern, deren erste Kammer (68) mit einem besagten Rohrstrang (46) und deren zweite Kammer mit dem den Zündkopf umgebenden Bohrungsringraum in Fluidverbindung steht; ein unter Ansprechen auf Fluiddruck im ersten Kammergehäuse beweglicher Betätigungskolben (140); und eine Auslöseanordnung (82), die aufweist, einen Zündkolben (114), eine Verriegelungsanordnung (116) zur Halterung des Zündkolbens in einer ersten Stellung, welche Verriegelungsanordnung durch die Bewegung des Betätigungskolbens lösbar ist, Mittel zur Auslösung der Bewegung des Schlagkolbens unter Ansprechen auf Druck in der zweiten Kammer des Gehäuses nach Lösen der Verriegelungsanordnung.

5. Vorrichtung nach Anspruch 4, dadurch gekennzeichnet, daß die Mittel zur Auslösung der Bewegung des Schlagkolbens unter Ansprechen auf Druck in der zweiten Kammer eine dritte Kammer (128) auf einer Seite eines Teils des Schlagkolbens aufweisen und daß die dritte Kammer im wesentlichen unter Atmosphärendruck steht.

6. Verfahren zum Perforieren einer Bohrung (12) und einer die Bohrung umgebenden Formation (18, 20), enthaltend die Schritte: Bereitstellen eines ersten Werkzeugstranges (24), eines ersten Packers (28), einer Perforierkanone (32) und eines ersten Zündkopfes (52), der auf Fluiddruck in dem Rohrstrang anspricht, in der Bohrung, dadurch gekennzeichnet, daß ein zweiter Zündkopf (58) auf Fluiddruck in dem Rohrstrang anspricht und die Perforierkanone (32) an einem Ende mit dem ersten Zündkopf und an einem zweiten Ende mit dem zweiten Zündkopf wirkgekoppelt wird, und daß in weiteren Schritten in der Bohrung ein zweiter Werkzeugstrang (26) bereitgestellt wird, der einen Strömungsweg von unterhalb des ersten Packers zur Oberfläche bildet, in der Bohrung an der zu perforierenden Zone unter Verwendung des zweiten Werkzeugstranges ein Druck eingestellt wird, und die Betätigung der ersten und zweiten Zündköpfe dadurch ausgelöst wird, daß in dem ersten Werkzeugstrang ein Fluiddruck eingestellt wird.

7. Verfahren nach Anspruch 6, dadurch gekennzeichnet, daß der erste Werkzeugstrang einen zweiten Packer (34) aufweist, der sich unter der ersten zu perforierenden Zone befindet; eine unter dem zweiten Packer angekoppelte Perforierkanone (40); einen mit der Perforierkanone wirkgekoppelten Zündkopf (38); und ein

mit Öffnungen versehenes Glied (36) zur Herstellung eines Strömungsweges von unterhalb des zweiten Packers in den ersten Werkzeugstrang.

8. Verfahren nach Anspruch 6 und 7, dadurch gekennzeichnet, daß der erste Werkzeugstrang ferner einen dritten Zündkopf aufweist, der auf Fluiddruck in dem Rohrstrang anspricht; einen vierten Zündkopf, der auf Fluiddruck in dem Rohrstrang anspricht; und eine zweite Perforierkanone (32b), die an einem Ende mit dem dritten Zündkopf und an einem zweiten Ende mit dem zweiten Zündkopf wirkgekoppelt ist.

Revendications

1. Dispositif de perforation d'un puits, comportant : un packer (28); un premier train d'outil (24) s'étendant à travers ledit packer et comportant au moins un ensemble (30a) de perforation, ledit ensemble de perforation comportant un train de tubes (25), un canon perforateur (32; 32a), un premier ensemble (52) formant tête de mise à feu pouvant être actionné par une pression de fluide située dans ledit train de tubes, caractérisé en ce qu'il comporte en outre un second ensemble (58) formant tête de mise à feu pouvant être actionné par une pression de fluide située dans ledit train de tubes, ledit canon perforateur (32; 32a) relié de manière active à proximité d'une extrémité à ladite première tête de mise à feu et relié de manière active à proximité d'une seconde extrémité à ladite seconde tête de mise à feu; et un second train d'outil (26) fournissant un passage pour l'écoulement de fluide à partir d'un emplacement situé au-dessous dudit packer jusqu'à la surface.

2. Dispositif selon la revendication 1, dans lequel ledit premier train d'outil comporte en outre : un second packer (34), ledit second packer étant situé au-dessous dudit ensemble perforateur; un second canon perforateur (40) relié au-dessous dudit second packer; des moyens (38) reliés de manière active audit second canon perforateur pour mettre en oeuvre ledit second canon perforateur; et un élément (36) à orifices couplé dans ledit train d'outil pour fournir un trajet d'écoulement depuis le dessous dudit second packer jusque dans le dit premier train d'outil.

3. Dispositif selon la revendication 1 ou 2, dans lequel ledit premier train d'outil comporte en outre un second ensemble (30b) perforateur, ledit second ensemble perforateur comportant

: un troisième ensemble formant tête de mise à feu pouvant être actionné par une pression de fluide dans ledit train de tubes un quatrième ensemble formant tête de mise à feu pouvant être actionné par une pression de fluide dans le dit train de tubes, et un second canon perforateur (32b) relié de manière active à proximité d'une extrémité audit troisième ensemble formant tête de mise à feu et relié de manière active à proximité de ladite seconde extrémité audit quatrième ensemble formant tête de mise à feu.

4. Dispositif selon l'une quelconque des revendications précédentes, comportant au-moins une tête de mise à feu (52, 58) comportant : un boîtier (62, 63) comportant une première (68) et une seconde chambres, ladite première chambre (68) étant en communication de fluide avec un train de tubes (46) et ladite seconde chambre étant en communication de fluide avec l'annulaire du puits entourant ladite tête de mise à feu; un piston actionneur (140) pouvant se déplacer en réponse à une pression de fluide dans ledit boîtier formant première chambre; et un ensemble formant détonateur (82) comportant un piston de mise à feu (114), un ensemble de blocage (116) destiné à retenir le piston de mise à feu dans une première position, ledit ensemble de blocage pouvant être libéré par déplacement dudit piston actionneur, des moyens pour provoquer le déplacement dudit piston formant percuteur en réponse à une pression dans ladite seconde chambre dudit boîtier après que ledit ensemble de blocage ait été libéré.
5. Appareil selon la revendication 4, dans lequel lesdits moyens pour provoquer le déplacement dudit piston formant percuteur en réponse à une pression dans ladite seconde chambre comporte une troisième chambre (128) située sur un côté d'une partie dudit piston formant percuteur, ladite troisième chambre étant à peu près à la pression atmosphérique.
6. Procédé de perforation d'un puits (12) et d'une formation (18,20) entourant ledit puits, comportant les étapes consistant à fournir dans ledit puits un premier train d'outil comportant un train de tubes (24), un premier packer (28), un canon perforateur (32), une première tête (52) de mise à feu sensible à une pression de fluide dans ledit train de tubes, caractérisé en ce qu'une seconde tête (58) de mise à feu est sensible à une pression de fluide dans ledit train de tubes, et ledit canon perforateur (32) est relié de manière active à proximité d'une

extrémité à ladite première tête de mise à feu et relié de manière active à proximité d'une seconde extrémité à ladite seconde tête de mise à feu, et en ce qu'il comporte en outre les étapes consistant à fournir un second train d'outil (26) dans ledit puits, ledit second train d'outil fournissant un trajet d'écoulement à partir du dessous dudit premier packer jusqu'à la surface, à établir une pression dans ledit puits au voisinage de ladite zone à perforer par utilisation dudit second train d'outil, et provoquer l'actionnement desdites première et seconde têtes de mise à feu en établissant une pression de fluide dans ledit premier train d'outil.

7. Procédé selon la revendication 6, dans lequel ledit premier train d'outil comporte en outre un second packer (34) situé au-dessous de ladite première zone à perforer; un canon perforateur (40) relié au-dessous dudit second packer; une tête (38) de mise à feu reliée de manière active audit canon perforateur; et un élément (36) à orifices pour établir un trajet d'écoulement à partir du dessous dudit second packer jusque dans le dit premier train d'outil.
8. Procédé selon la revendication 6 et 7, dans lequel ledit premier train d'outil comporte en outre une troisième tête de mise à feu sensible à une pression de fluide dans ledit train de tubes; une quatrième tête de mise à feu sensible à une pression de fluide dans ledit train de tubes; et un second canon perforateur (32b) relié de manière active à proximité d'une première extrémité de ladite troisième tête de mise à feu et relié de manière active à proximité d'une seconde extrémité à ladite seconde tête de mise à feu.
